1

Given a function f , evaluated at the points $x \pm \delta$ and $x \pm 2\delta$.

1.1 a)

The derivative at x can be calculated from the points around x using the central derivative formula (in the limit of small δ):

$$f'(x) = \frac{f(x + \delta) - f(x - \delta)}{2\delta}$$

Performing a Taylor expansion of f at each point gives

$$f(x + \delta) \approx f(x) + f'(x)\delta + \frac{1}{2}f''(x)\delta^2 + \frac{1}{6}f'''(x)\delta^3 + \frac{1}{24}f''''(x)\delta^4 + \frac{1}{120}f'''''(x)\delta^5 + \dots$$

$$f(x - \delta) \approx f(x) - f'(x)\delta + \frac{1}{2}f''(x)\delta^2 - \frac{1}{6}f'''(x)\delta^3 + \frac{1}{24}f''''(x)\delta^4 - \frac{1}{120}f'''''(x)\delta^5 + \dots$$

$$f(x + 2\delta) \approx f(x) + f'(x)2\delta + 2f''(x)\delta^2 + \frac{4}{3}f'''(x)\delta^3 + \frac{2}{3}f''''(x)\delta^4 + \frac{4}{15}f'''''(x)\delta^5 + \dots$$

$$f(x - 2\delta) \approx f(x) - f'(x)2\delta + 2f''(x)\delta^2 - \frac{4}{3}f'''(x)\delta^3 + \frac{2}{3}f''''(x)\delta^4 - \frac{4}{15}f'''''(x)\delta^5 + \dots$$

For the $x \pm \delta$ case, subtracting $f(x - \delta)$ from $f(x + \delta)$ gives the central derivative:

$$f(x + \delta) - f(x - \delta) = 2f'(x)\delta + \frac{1}{3}f'''(x)\delta^3 + \frac{1}{60}f'''''(x)\delta^5 + \dots$$

$$f'(x) = \frac{f(x + \delta) - f(x - \delta)}{2\delta} - \frac{1}{6}f'''(x)\delta^2 - \frac{1}{120}f'''''(x)\delta^4 + \dots$$

Performing the same operation on the $x \pm 2\delta$ case:

$$f'(x) = \frac{f(x + 2\delta) - f(x - 2\delta)}{4\delta} - \frac{2}{3}f'''(x)\delta^2 - \frac{2}{15}f'''''(x)\delta^4 - \dots$$

The δ^2 term can be eliminated by subtracting four times the $x \pm \delta$ derivative from the $x \pm 2\delta$ derivative

$$\begin{aligned} f'(x) - 4f'(x) &= \left(\frac{f(x + 2\delta) - f(x - 2\delta)}{4\delta} - \frac{2}{3}f'''(x)\delta^2 - \frac{2}{15}f'''''(x)\delta^4 - \dots \right) - \\ &\quad 4 \left(\frac{f(x + \delta) - f(x - \delta)}{2\delta} - \frac{1}{6}f'''(x)\delta^2 - \frac{1}{120}f'''''(x)\delta^4 + \dots \right) \\ -3f'(x) &= \frac{8f(x - \delta) + f(x + 2\delta) - 8f(x + \delta) - f(x - \delta)}{4\delta} - \frac{1}{10}f'''''(x)\delta^4 \end{aligned}$$

$$\boxed{f'(x) = \frac{8f(x + \delta) - 8f(x - \delta) + f(x - \delta) - f(x + 2\delta)}{12\delta} + \frac{1}{30}f'''''(x)\delta^4 + \dots}$$

1.2 b)

The error for this derivative is comes from rounding error and discarding higher order terms from the Taylor series. For rounding error ϵ , the error is approximately

$$\text{error} = \frac{|f(x)| \cdot \epsilon}{\delta} + \frac{1}{30} f''''(x) \delta^4.$$

Minimizing with respect to δ :

$$0 = \frac{d}{d\delta} \left(\frac{|f(x)| \cdot \epsilon}{\delta} + \frac{1}{30} f''''(x) \delta^4 \right) = -\frac{|f(x)| \cdot \epsilon}{\delta^2} + \frac{2}{15} f''''(x) \delta^3$$

$$\frac{|f(x)| \cdot \epsilon}{\delta^2} = \frac{2}{15} f''''(x) \delta^3$$

$$\delta^5 = \frac{15}{2} \frac{|f(x)| \cdot \epsilon}{f''''(x)}$$

So the ideal value of δ should be

$$\delta = \left(\frac{15}{2} \frac{|f(x)| \cdot \epsilon}{f''''(x)} \right)^{1/5}.$$
